

20. Your friends are involved in a large-scale atmospheric science experiment. They need to get good measurements on a set S of n different conditions in the atmosphere (such as the ozone level at various places), and they have a set of m balloons that they plan to send up to make these measurements. Each balloon can make at most two measurements.

Unfortunately, not all balloons are capable of measuring all conditions, so for each balloon $i = 1, \dots, m$, they have a set S_i of conditions that balloon i can measure. Finally, to make the results more reliable, they plan to take each measurement from at least k different balloons. (Note that a single balloon should not measure the same condition twice.) They are having trouble figuring out which conditions to measure on which balloon.

Example. Suppose that $k = 2$, there are $n = 4$ conditions labeled c_1, c_2, c_3, c_4 , and there are $m = 4$ balloons that can measure conditions, subject to the limitation that $S_1 = S_2 = \{c_1, c_2, c_3\}$, and $S_3 = S_4 = \{c_1, c_3, c_4\}$. Then one possible way to make sure that each condition is measured at least $k = 2$ times is to have

- balloon 1 measure conditions c_1, c_2 ,
 - balloon 2 measure conditions c_2, c_3 ,
 - balloon 3 measure conditions c_3, c_4 , and
 - balloon 4 measure conditions c_1, c_4 .
- (a) Give a polynomial-time algorithm that takes the input to an instance of this problem (the n conditions, the sets S_i for each of the m balloons, and the parameter k) and decides whether there is a way to measure each condition by k different balloons, while each balloon only measures at most two conditions.
