

Chapter 6

The t-test and Basic Inference Principles

This chapter is used as an example of the basic principles of statistical inference.

One of the simplest situations for which we might design an experiment is the case of a nominal two-level explanatory variable and a quantitative response variable. Table 6.1 shows several examples. For all of these experiments, the treatment factor is nominal, and the treatment variable is nominal. None of the other explanatory variables (the two levels of treatment) are being compared for these examples. If we randomly assign the treatments to these units, this will be a randomized experiment rather than an observational study, so we will be able to apply the word “cause” rather than just “is associated with” to any statistically significant results. This chapter may discuss so-called “behavior outcomes” experimentally associated, while saying that we are assuming that such experimental unit is exposed to only one of the two levels of treatment (even though, that is not necessarily the most obvious way to run the RCT experiment).

This chapter shows one way to perform statistical inference for the two-group quantitative outcome experiment, namely the independent samples t-test. That is, naturally, the focus is on an example for demonstrating the basic principles of statistical inference that will be used throughout the book. The randomization of these participants, along with some degree of theoretical underpinning, is key to using statistical results intelligently. Among other things, you want to make sure that a positive and a negative result tell us, and when there are
