Abstract: The aim of this study was to compare the efficacy of chemomechanical methods (Carisolv™ and Papacárie®) versus the manual method (excavators) in reducing the cariogenic microbiota in dentine caries of primary teeth. Forty-six healthy children (5 to 9 years old) having at least one primary tooth with a cavitated dentine carious lesion were included in the study. The teeth presented no clinical or radiographic signs of pulpal involvement. The sample of 74 teeth was randomly divided into three different groups: Papacárie® (n = 25), Carisolv™ (n = 27) and Manual (n = 22). Samples of carious and sound dentine were collected with sterile excavators before and after caries removal in the three groups. The dentine samples were transferred to glass tubes containing a 1mL thioglycollate medium used as a carrier and enriched for microbiological detection of mutans streptococci and Lactobacillus spp. after incubation for 6h at room temperature. The minimum detection value for colony forming units (CFU) was 3.3×10^2 CFU/ml, and the results were converted into scores from 0 to 4. A significant difference was observed in relation to the microbiological scores before and after caries removal for all methods (Wilcoxon test; $p < 0.001$). The use of chemomechanical methods for caries removal did not improve the reduction of cariogenic microorganisms in dentine caries lesions, in comparison with manual excavation.

Keywords: Dental Caries; Papain; Microbiology; Tooth, Deciduous.

Introduction

The therapeutic approach to carious dentine lesions has been reconsidered by the scientific community over time as a way to preserve as much tooth structure as possible, increase the longevity of teeth and prevent the repetitive restorative cycle.^{1,2,3} Based on the minimal invasive dentistry concept, more conservative approaches have been recommended,^{4,5} such as partial caries removal,⁶ atraumatic restorative treatment⁷ and chemomechanical methods,^{8,9} instead of conventional caries removal by drilling and manual excavation.

Although the chemomechanical system was developed over 30 years ago, it only started to gain attention in the late 90s, when Carisolv™ was released on the market and began to be used widely. This system involves application of a gel composed of an amino acid solution and sodium hypochlorite, which are able to dissolve collagen fibers degraded
