Further Use of Spread Footing Foundations for Highway Bridges Shad M. Sargand, 2006 Spread footing foundations have been used to support various types of civil engineering structures over the years However one type of structure to which they have not seen much widespread application is highway bridges This is because bridge engineers generally take a rather conservative approach and specify deep foundations such as H piles and drilled pier shafts to support the bridge superstructure weight and live loads In the current research project the ORITE team continued to investigate several technical aspects related to spread footing

foundations Four additional spread footings constructed at two interstate highway construction sites were instrumented with modern sensors and monitored through construction stages and beyond The spread footing design methods presented in the AASHTO LRFD Bridge Design Specifications 2004 were validated on the basis of the field performance data accumulated during the ORITE research project s Twelve SPT based settlement prediction methods for footings resting on cohesionless or slightly cohesive soils were evaluated in light of the field performance data General performance analysis of spread footing foundations at bridge construction sites was made to draw some guidelines concerning the use of spread footings for supporting highway bridge structures Finally detailed cost comparisons were made between spread footing and pile foundation options Overall the results of the research project indicated that 1 spread footing can be a viable option as the highway bridge foundation and 2 the design methods presented in the AASHTO LRFD Bridge Design Specifications 2004 appear to be satisfactory *Redundancy in Highway Bridge Substructures* Wen David Liu,2001 **Analyzing and**

Designing for Substructure Movement in Highway Bridges Dustin Schopen,2010 Movement of bridge substructures can adversely affect the strength and serviceability of bridge superstructures Research concluded in 1985 utilized field and analytical studies to create tolerable bridge movement limits Because the limits were determined based on the design and loading provisions of the American Association of State Highway and Transportation Officials AASHTO Standard Specifications for Highway Bridges there was a need for the previous research to be reproduced and updated based on the provisions of the AASHTO Load and Resistance Factor Design LRFD Bridge Design Specifications Simple two dimensional analytical models and models of actual in service highway bridges were analyzed in order to study the effects of differential vertical movement The results obtained from the analyses suggested that in general the reserve moment capacities of bridge girders are sufficient to resist the additional stresses caused by differential settlement of bridge substructures Despite the ability of most bridges to tolerate small magnitudes of differential vertical substructure movement expected movements should be accounted for during the design process to ensure that safety and reliability are maintained A method of calculating the effects of anticipated differential settlements was determined It is recommended that force effects associated with anticipated differential vertical movements of substructures be included in the design of bridge girders **Bridge**
