Sediment Transport Modeling In Hec Ras:

Sediment Transport in Aquatic Environments Andrew Manning, 2011-10-03 Sediment Transport in Aquatic Environments is a book which covers a wide range of topics The effective management of many aquatic environments requires a detailed understanding of sediment dynamics This has both environmental and economic implications especially where there is any anthropogenic involvement Numerical models are often the tool used for predicting the transport and fate of sediment movement in these situations as they can estimate the various spatial and temporal fluxes However the physical sedimentary processes can vary quite considerably depending upon whether the local sediments are fully cohesive non cohesive or a mixture of both types For this reason for more than half a century scientists engineers hydrologists and mathematicians have all been continuing to conduct research into the many aspects which influence sediment transport These issues range from processes such as erosion and deposition to how sediment process observations can be applied in sediment transport modeling frameworks This book reports the findings from recent research in applied sediment transport which has been conducted in a wide range of aquatic environments The research was carried out by researchers who specialize in the transport of sediments and related issues I highly recommend this textbook to both scientists and engineers who deal with sediment transport issues

Application of HEC-RAS Model to Predict Sediment Transport for Two Reservoirs Bedriye Nur Dikenli, 2018 Version 5 0 3 of the Hydrologic Engineering Center's River Analysis System HEC RAS includes an array of new sediment transport capabilities Previous HEC RAS versions 5 0 were limited to quasi unsteady flow and vertical bed change Recent versions of HEC RAS include sediment transport with HEC RAS unsteady flow new bed change algorithms cohesive transport approaches armoring methods and an array of new output options Gibson 2017 In this thesis the new one dimensional 1D sediment capabilities of HEC RAS 5 0 3 were applied on the Foster Joseph Sayers Reservoir despite lack of knowledge about sediment load and the grain size distribution of the bed after deposition and erosion Three transport equations namely Ackers White Engelund Hansen and Laursen were applied with both quasi unsteady and unsteady sediment simulations of the Foster Joseph Sayers Reservoir To overcome the uncertainty of grain size distribution during the simulation four different cases were created for the Ackers White equation In these four cases different values of the calibration parameters within Ackers White a coefficient to calculate sediment transport parameter critical sediment mobility parameter and an exponent to calculate sediment transport parameter were applied These calibration parameters are determined by the d35 value To understand the impact of the different sediment transport equations Engelund Hansen Laursen and the four cases of Ackers White equations were also applied to the Mosul Reservoir using the quasi unsteady sediment method of HEC RAS 5 0 3 Data used in this work include Digital Elevation Models DEMs cross section measurements and hydrologic observations

[Application of Agisoft Photoscan and Sediment Transport Modeling for the Analysis of Sediment Wave Propagation Succeeding Gravel Augmentation, Oak Grove Fork of the Clackamas River, Oregon](#)

Mindi Lea Curran, 2017 Physical features in alluvial rivers such as riffles gravel bars pools and side channels provide refugia nutrients and spawning and rearing habitat for anadromous fish and other aquatic organisms The downstream transport of gravels that continuously replenish these features is prevented by dams and often leads to a coarsened channel bed condition and other geomorphic changes that have negative impacts on aquatic organisms Geomorphic change in rivers can be challenging to capture in high resolution making the propagation and distribution of sediment difficult to quantify especially if the deposition occurs in small quantities or thin layers One solution for replenishing physical features that have been cut off from gravel supply downstream of dams is gravel augmentation This thesis uses two independent methods to investigate

the transport and storage of augmented gravels as they route downstream 1 topographic change detection using photogrammetry and differencing of Digital Terrain Models DTMs and 2 a 1D sediment transport model created in HEC RAS Hydrologic Engineering Centers River Analysis System to model flow and sediment scenarios Together these methods are used to investigate sediment wave propagation and channel response to augmented gravels The location of study is the Oak Grove Fork OGF one of the largest tributaries of the Clackamas River located in northwestern Oregon The Lake Harriet Dam and diversion were built on the OGF in 1924 as part of a hydroelectric development project by Portland General Electric Decreased flow and sediment supply downstream of Lake Harriet Dam has resulted in geomorphic and biological changes including reduced salmonid habitat leading to a mandated gravel augmentation program that began in September of 2016 which introduced 250 tons of gravel into the river High resolution DTMs generated using photogrammetry captured topographic change at sites on the order of tenths of feet with vertical accuracy also on the order of tenths of feet All change detected at photogrammetry sites within one year of augmentation was determined to be a record of typical natural year to year change and is not attributed to transport and deposition of augmented gravels The 1D sediment transport model suggests that peak flows exceeding 1 200 cfs are the primary driving factors of sediment transport and that higher peak flows exceeding those seen in 2016 and 2017 will be required to transport the augmented gravels downstream 0.81 miles past a naturally occurring fish barrier waterfall to where anadromous fish habitat begins A storage capacity estimate calculation suggests that up to 600 tons of gravel could fill interstitial spaces between existing boulders and cobbles as gravel routes downstream past Barrier Falls and into accessible habitat

Channel-conveyance capacity, channel change, and sediment transport in the lower Puyallup, White, and Carbon Rivers, western Washington Jonathan A. Czuba, Christiana R. Czuba, Christopher S. Magirl, Frank D. Voss, 2010-12-01 Draining the volcanic glaciated terrain of Mount Rainier Washington the Puyallup White and Carbon Rivers convey copious volumes of water and sediment down to Commencement Bay in Puget Sound Recent flooding in the lowland river system has renewed interest in understanding sediment transport and its effects on flow conveyance throughout the lower drainage basin Bathymetric and topographic data for 156 cross sections were surveyed in the lower Puyallup River system by the U S Geological Survey USGS and were compared with similar datasets collected in 1984 Regions of significant aggradation were measured along the Puyallup and White Rivers Between 1984 and 2009 aggradation totals as measured by changes in average channel elevation were as much as 7.565 and 2 feet on the Puyallup White and Carbon Rivers respectively These aggrading river sections correlated with decreasing slopes in riverbeds where the rivers exit relatively confined sections in the upper drainage and enter the relatively unconstricted valleys of the low gradient Puget Lowland Measured grain size distributions from each riverbed showed a progressive fining downstream Analysis of stage discharge relations at streamflow gaging stations along rivers draining

The Effects of Restoration Modeling on

Channel-conveyance capacity, channel change,

Mount Rainier demonstrated the dynamic nature of channel morphology on river courses influenced by glaciated volcanic terrain. The greatest rates of aggradation since the 1980s were in the Nisqually River near National 50 inches per year and the White River near Auburn 18 inches per year. Less pronounced aggradation was measured on the Puyallup River and the White River just downstream of Mud Mountain Dam. The largest measured rate of incision was measured in the Cowlitz River at Packwood 50 inches per year. Channel conveyance capacity estimated using a one dimensional hydraulic model decreased in some river reaches since 1984. The reach exhibiting the largest decrease about 20-50 percent in channel conveyance capacity was the White River between R Street Bridge and the Lake Tapps return a reach affected by recent flooding. Conveyance capacity also decreased in sections of the Puyallup River. Conveyance capacity was mostly unchanged along other study reaches. Bedload transport was simulated throughout the entire river network and consistent with other observations and analyses the hydraulic model showed that the upper Puyallup and White Rivers tended to accumulate sediment. Accuracy of the bedload transport modeling however was limited due to a scarcity of sediment transport data sets from the Puyallup system mantling of sand over cobbles in the lower Puyallup and White Rivers and overall uncertainty in modeling sediment transport in gravel bedded rivers. Consequently the output results from the model were treated as more qualitative in value useful in comparing geomorphic trends within different river reaches but not accurate in producing precise predictions of mass of sediment moved or deposited. The hydraulic model and the bedload transport component were useful for analyzing proposed river management options if surveyed cross sections adequately represented the river management site and proposed management options. The hydraulic model showed that setback levees would provide greater flood protection than gravel bar scalping after the initial project construction and for some time thereafter although the model was not accurate enough to quantify the length of time of the flood protection. The greatest hydraulic benefit from setback levees would be a substantial increase in the effective channel conveyance area. By widening the distance between levees the new floodplain would accommodate larger increases in discharge with relatively small incremental increases in stage. Model simulation results indicate that the hydraulic benefit from a setback levee also would be long lived and would effectively compensate for increased deposition within the setback reach from increased channel conveyance capacity. In contrast the benefit from gravel bar scalping would be limited by the volume of material that could be removed and the underlying hydraulics in the river section that would be mostly unaffected by scalping. Finally the study formulated an explanation of the flooding that affected Pacific Washington in January 2009. Reduction in channel conveyance capacity of about 25 percent at the White River near Auburn streamflow gaging station between November 2008 and January 2009 was caused by rapid accumulation of coarse grained sediment just downstream of the gage continuing an ongoing trend of aggradation that has been documented repeatedly.
