The Lost Foam Casting Process:

Program Management and the Lost Foam Casting Process Greg Sanders, 2000 Modeling of Metal/pattern Replacement in the Lost Foam Casting Process Taras Molibog, 2002 *Mold Filling in the Lost Foam Casting Process* Ron Paul Walling, 1992 **Gating Design and Mold Filling in the Lost Foam Casting Process** Mickey Dean Lawrence, 1995

Gating and mold filling of castings in the lost foam casting process have been studied to determine the importance of processing parameters and how these parameters can be used to control mold filling. The research in paper 1 describes the statistically significant effects of processing parameters and gating system design for an industry type hat shaped pattern on mold filling characteristics such as fill time, horizontal velocities and vertical velocities. The permeability of the refractory coating is the most important variable. The metallostatic pressure head and the pouring temperature also affected the mold filling characteristics to a smaller degree. A maximum velocity about 1 in/s cannot be exceeded if a sound casting is to be produced. Paper 2 describes how processing parameters might be used to predict and control the mold filling in the lost foam casting process. The research involved four steps. Step 1 which used a pattern for a tube holder for a heat exchanger the pendant pattern explored ways to force the pattern to fill faster than the runner and to skew the progressing metal front towards the gates in order to force any foam decomposition products into the gating system. Although some improvements were made this was only accomplished when a straight plate pattern was substituted for the curved pendant pattern. Step 2 used the information from step 1 and previous work to produce a model which predicted the position of the molten metal front throughout the filling process of a pump housing pattern. It was found that intersections involving sharp direction changes from vertical to horizontal flow have a sizable effect on the velocity of the molten metal front as the pattern fills. The slope of the line when actual time was plotted versus the expected time also differed because the actual pattern had a higher density than those used to produce the model. Step 3 explored in more detail the effect that sharp direction changes have on mold filling characteristics in simple plate patterns. The effect of the intersection on the flow of the molten aluminum was confirmed. The change in velocity was measured as a jump in the elapsed time when plotted against the predicted time. Step 4 included the effect of the intersection on the predicted metal front progression in an industry type pipe pattern casting. The predictions were not confirmed suggests that the effect of intersections is more complex expected. More research on the effect of direction changes must be performed in order to make a model that accurately predicts mold filling in the lost foam process. Abstract leaves iv v **A Methodology for Monitoring the Metal-fill in Lost Foam Casting Process** Jeanison Pradeep Arulanantham, 2005 **Lost Foam Castings in Steel: Determination of the Foam Displacement Mechanism and Carbon Pick-up** Siddharth Gupta, 2008. Lost foam casting process has been widely adopted to manufacture complex parts without the need for cores. Numeric modeling of expanded polystyrene (EPS) foam displacement is only recently reaching a point where it can provide useful insight in helping optimize design and process variables. Report Quantification and Standardization of Pattern Properties for the Control of the Lost Foam Casting Process

,2005 This project takes a fresh look at the white side of the lost foam casting process We have developed the gel front hypothesis for foam pyrolysis behavior and the magnetic metal pump method for controlling lost foam casting metal fill event The subject of this report is work done in the improvement of the Lost Foam Casting Process The original objective of this project was to improve the control of metal fill by understanding the influence of foam pattern and coating properties on the metal fill event Relevant pattern properties could then be controlled providing control of the metal fill event One of the original premises of this project was that the process of metal fill was relatively well understood Considerable previous work had been done to develop fluid mechanical and heat transfer models of the process If we could just incorporate measured pattern properties into these models we would be able predict accurately the metal fill event As we began to study the pyrolysis behavior of EPS during the metal fill event we discovered that the chemical nature of this event had been completely overlooked in previous research Styrene is the most prevalent breakdown product of EPS pyrolysis and it is a solvent for polystyrene Much of the styrene generated by foam pyrolysis diffuses into intact foam producing a molten gel of mechanically entangled polystyrene molecules Much of the work of our project has centered on validation of this concept and producing a qualitative model of the behavior of EPS foam undergoing pyrolysis in a confined environment A conclusion of this report is that styrene dissolution in EPS is a key phenomenon in the pyrolysis process and deserves considerable further study While it is possible to continue to model the metal fill event parametrically using empirical data we recommend that work be undertaken by qualified researchers to directly characterize and quantify this phenomenon for the benefit of modelers researchers and workers in the field Another original premise of this project was that foam pattern and coating properties could be used to efficiently control metal fill After studying the structure of EPS foam in detail for the period of this contract we have come to the conclusion that EPS foam has an inherent variability at a scale that influences metal fill behavior This does not allow for the detailed fine control of the process that we originally envisioned We therefore have sought other methods for the control of the metal fill event Of those we now believe that the magnetic metal pump shows the most promise We have conducted two casting trials using this method and preliminary results are very encouraging A conclusion of our report is that while every effort should continue to be made to produce uniform foam and coatings the use of the magnetic metal pump should be encouraged and closed loop control mechanisms should be developed for this pouring
