Introduction

The volume of outstanding OTC derivatives has grown exponentially over the past 15 years. Market surveys conducted by the International Swaps and Derivatives Association (ISDA) show notional amounts of outstanding interest rate and currency swaps reaching US\$866 billion in 1987, US\$17.7 trillion in 1995, and US\$99.8 trillion in 2002; an astonishing compounded growth rate of 37.2% per year.¹ Derivatives have expanded the opportunities to transfer risks, allowing for substantially improved risk sharing. They have also created connections among markets and market participants that are only just starting to be understood.

Counterparty risk, an example of one such connection, is the risk that a party to an OTC derivatives contract may fail to perform on its contractual obligations, causing losses to the other party. Losses are usually quantified in terms of the replacement cost of the defaulted derivatives and include, beyond mid-market values, the potential market impact of large and/or illiquid positions. Counterparty risks are bilateral – ie, both parties may face exposures depending on the value of the positions they hold against each other. Counterparty risks have mushroomed in the financial markets due to (a) the usual practice of ‘offsetting’ rather than ‘unwinding’ derivative positions and (b) the array of inter-dealer trades required to connect final risk-takers.

OTC derivatives and counterparty risks are focal points for market participants, policy-makers, regulators, accountants, tax authorities and many others. This chapter is an overview of the key issues relating to the measurement and pricing of counterparty risks.

Counterparty exposures

Definitions

- *Counterparty exposure* is the larger of zero and the market value of the portfolio of derivative positions with a counterparty that would be lost if the counterparty were to default and there were zero recovery. Counterparty exposures created by OTC derivatives are usually only a small fraction of the total notional amount of trades with a counterparty.
- *Current exposure* (CE) is the current value of the exposure to a counterparty.
- *Potential future exposure* (PFE) is the maximum amount of exposure expected to occur on a future date with a high degree of statistical confidence. For example, the 95% PFE is the

Measuring a Counterparty Credit Exposure to a Margined Counterparty Michael S. Gibson, 2005 Firms active in OTC derivative markets increasingly use margin agreements to reduce counterparty credit risk Making several simplifying assumptions I use both a quasi analytic approach and a simulation approach to quantify how margining reduces counterparty credit exposure Margining reduces counterparty credit exposure by over 80 percent using baseline parameter assumptions I show how expected positive exposure EPE depends on key terms of the margin agreement and the current mark to market value of the portfolio of contracts with the counterparty I also discuss a possible shortcut that could be used by firms that can model EPE without margin but cannot achieve the higher level of sophistication needed to model EPE with margin

Bounding Wrong-Way Risk in Measuring Counterparty Risk Paul Glasserman, 2015 Counterparty risk measurement integrates two sources of risk market risk which determines the size of a firm's exposure to a counter party and credit risk which reflects the likelihood that the counterparty will default on its

obligations Wrong way risk refers to the possibility that a counterparty's default risk increases with the market value of the exposure We investigate the potential impact of wrong way risk in calculating a credit valuation adjustment CVA to a derivatives portfolio CVA has become a standard tool for pricing counterparty risk and setting associated capital requirements We present a method introduced in our earlier work for bounding the impact of wrong way risk on CVA The method holds fixed marginal models for market and credit risk while varying the dependence between them Given simulated paths of the two models we solve a linear program to find the worst case CVA resulting from wrong way risk The worst case can be overly conservative so we extend the procedure by penalizing deviations of the joint model from a baseline model By varying the penalty for deviations we can sweep out the full range of possible CVA values for different degrees of wrong way risk Our method addresses an important source of model risk in counterparty risk measurement
