Dynamical Systems In Population Biology:

Dynamical Systems in Population Biology Xiao-Qiang Zhao, 2013-06-05 Population dynamics is an important subject in mathematical biology. A central problem is to study the long term behavior of modeling systems. Most of these systems are governed by various evolutionary equations such as difference, ordinary functional and partial differential equations (see e.g. [165, 142, 218, 119, 55]). As we know, interactive populations often live in a fluctuating environment. For example, physical environmental conditions such as temperature and humidity and the availability of food, water and other resources usually vary in time with seasonal or daily variations. Therefore, more realistic models should be nonautonomous systems. In particular, if the data in a model are periodic functions of time with commensurate period, a periodic system arises. If these periodic functions have different minimal periods, we get an almost periodic system. The existing reference books from the dynamical systems point of view mainly focus on autonomous biological systems. The book of Hess [106] is an excellent reference for periodic parabolic boundary value problems with applications to population dynamics. Since the publication of this book, there have been extensive investigations on periodic, asymptotically periodic, almost periodic and even general nonautonomous biological systems, which in turn have motivated further development of the theory of dynamical systems. In order to explain the dynamical systems approach to periodic population problems, let us consider as an illustration two species periodic competitive systems.

Dynamical Systems and Population Persistence Hal L. Smith, Horst R. Thieme, 2011 The mathematical theory of persistence answers questions such as which species in a mathematical model of interacting species will survive over the long term. It applies to infinite dimensional as well as to finite dimensional dynamical systems and to discrete time as well as to continuous time semiflows. This monograph provides a self-contained treatment of persistence theory that is accessible to graduate students. The key results for deterministic autonomous systems are proved in full detail, such as the acyclicity theorem and the tripartition of a global compact attractor. Suitable conditions are given for persistence to imply strong persistence, even for nonautonomous semiflows, and time heterogeneous persistence results are developed using so-called average Lyapunov functions. Applications play a large role in the monograph from the beginning. These include ODE models such as an SEIRS infectious disease in a meta population and discrete time nonlinear matrix models of demographic dynamics. Entire chapters are devoted to infinite dimensional examples including an SI epidemic model with variable infectivity, microbial growth in a tubular bioreactor and an age structured model of cells growing in a chemostat.

Competition Models in Population Biology Paul Waltman, 1983-01-01 This book uses fundamental ideas in dynamical systems to answer questions of a biologic nature, in particular questions about the behavior of populations given a relatively few hypotheses about the nature of their growth and interaction. The principal subject treated is that of coexistence under certain parameter ranges, while asymptotic methods are used to show competitive exclusion in other parameter ranges. Finally, some problems in genetics are posed and analyzed as problems in nonlinear

Nonlinear Dynamics of Interacting Populations A. D. Bazykin, Aleksandr Iosifovich Khibnik, Bernd Krauskopf, 1998 This book contains a systematic study of ecological communities of two or three interacting populations Starting from the Lotka Volterra system various regulating factors are considered such as rates of birth and death predation and competition The different factors can have a stabilizing or a destabilizing effect on the community and their interplay leads to increasingly complicated behavior Studying and understanding this path to greater dynamical complexity of ecological systems constitutes the backbone of this book On the mathematical side the tool of choice is the qualitative theory of dynamical systems most importantly bifurcation theory which describes the dependence of a system on the parameters This approach allows one to find general patterns of behavior that are expected to be observed in ecological models Of special interest is the reaction of a given model to disturbances of its present state as well as to changes in the external conditions This leads to the general idea of dangerous boundaries in the state and parameter space of an ecological system The study of these boundaries allows one to analyze and predict qualitative and often sudden changes of the dynamics a much needed tool given the increasing antropogenic load on the biosphere As a spin off from this approach the book can be used as a guided tour of bifurcation theory from the viewpoint of application The interested reader will find a wealth of intriguing examples of how known bifurcations occur in applications The book can in fact be seen as bridging the gap between mathematical biology and bifurcation theory
