ABSTRACT: This paper discusses the design of timber diaphragms, in response to the growing interest in multi-storey commercial timber structures, and the lack of guidance or regulations regarding the seismic design of timber diaphragms.

Proper performance of floor diaphragms is required to transfer all lateral loads to the vertical systems that resist them, but design for earthquake loads can be more complex than design for wind loads. This paper confirms that the seismic design of a diaphragm is intimately linked to the seismic design of the whole building. Diaphragm failure, even if restricted to a limited diaphragm portion, can compromise the behaviour of the whole building. It is therefore necessary to design and detail diaphragms for all possible load paths and to evaluate their influence on the load distribution within the rest of the structure. It is strongly recommended that timber diaphragms be designed as elastic elements, by applying dynamic amplification and overstrength factors derived from the lateral load resisting system.

This paper shows that some current design recommendations for plywood sheathing on light timber framing can be applied to massive wood diaphragms, but for more complex floor geometries an equivalent truss method is suggested. Diaphragm flexibility and displacement incompatibilities between the floor diaphragms and the lateral resisting systems also need to be accounted for.

1 INTRODUCTION

Recent years have seen a growing interest in engineered multi-storey timber buildings around the world. A number of tall timber buildings have been built in Europe, followed by a 10 storey building in Melbourne (Binational Softwood Lumber Council et al. 2014). Both Canada and the US have set up design competitions in order to promote timber as the construction material for tall buildings. The New Zealand construction sector is part of this trend, with a number of commercial timber buildings already built (Ministry for Primary Industries 2014) or in the design process. The local availability of glued laminated timber (glulam), Cross Laminated Timber (CLT), Laminated Veneer Lumber (LVL) as well as prefabricated Light Timber Frame (LTF) elements and the soon to be released new NZ Timber Structures Standard are all encouraging the use of timber for new multi-residential, commercial and industrial buildings.

This new global interest in medium to high-rise multi-storey timber buildings creates the need for a more rigorous approach in design. Furthermore, the presence of some of these structures in seismically active countries has highlighted knowledge gaps regarding their performance under earthquake loading and especially in the design of diaphragms.

1.1 Role of diaphragms

Independently of the construction material used, diaphragms have a multiple role in the structural behaviour of a building. Aside from acting as slabs under gravity loads, diaphragms tie all other structural elements together and transfer horizontal loads to the vertical Lateral Load Resisting System (LLRS). Being the first element to resist most gravity and horizontal forces, a loss of diaphragm action will likely compromise the behaviour of the whole structure.

Use of Timber in Tall Multi-Storey Buildings Ian Smith, Andrea Frangi, 2014-01-01 Since the dawn of civilization timber has been a primary material for achieving great structural engineering feats Yet during the late 19th century and most of the 20th century it lost currency as a preferred material for construction of large and tall multi storey building superstructures This Structural Engineering Document SED addresses a reawakening of interest in timber and timber based products as primary construction materials for relatively tall multi storey buildings Emphasis throughout is on holistically addressing various aspects of performance of complete systems reflecting that major gaps in knowhow relate to design concepts rather than technical information about timber as a material Special consideration is given to structural form fire vulnerability and durability aspects for attaining desired building performance over lifespans that can be centuries long **Timber**

Buildings and Structures under Extreme Loads Chiara Bedon,Flavio Stochino,Daniel Honfi,2020-11-25 Exceptional loads on buildings and structures may have different causes including high strain dynamic effects due to natural hazards man made attacks and accidents as well as extreme operational conditions severe temperature variations humidity etc All of these aspects can be critical for specific structural typologies and or materials that are particularly sensitive to external conditions In this regard dedicated and refined methods are required for their design analysis and maintenance under the expected lifetime There are major challenges related to the structural typology and material properties with respect to the key features of the imposed design load Further issues can be derived from the need for risk mitigation or retrofit of existing structures as well as from the optimal and safe design of innovative materials systems Finally in some cases no appropriate design recommendations are available and thus experimental investigations can have a key role within the overall process In this Special Issue original research studies review papers and experimental and or numerical investigations are presented for the structural performance assessment of buildings and structures under various extreme conditions that are of interest for design
