Control of a Wind Driven Doubly Fed Induction Generator During Grid Faults Mahmoud

Mossa,2013-02-06 Master s Thesis from the year 2013 in the subject Engineering Power Engineering grade none course Electrical engineering Renewable energy language English abstract Wind electrical power systems are recently getting lot of attention because they are cost competitive environmental clean and safe renewable power source as compared with fossil fuel and nuclear power generation A special type of induction generator called a doubly fed induction generator DFIG is used extensively for high power wind applications They are used more and more in wind turbine applications due to ease controllability high energy efficiency and improved power quality This thesis aims to develop a method of a field orientation scheme for control both the active and reactive powers of a DFIG driven by a wind turbine The proposed control system consists of a wind turbine that drives a DFIG connected to the utility grid through AC DC AC link The main control objective is to regulate the dc link voltage for operation at maximum available wind power This is achieved by controlling the d and q components of voltages and currents for both rotor side and line side converters using PI controllers The complete dynamic model of the proposed system is described in detail Computer simulations have been carried out in order to validate the effectiveness of the proposed system during the variation of wind speed The results prove that better overall performances are achieved quick recover from wind speed disturbances in addition to good tracking ability Generally any abnormalities associated with grid asymmetrical faults are going to affect the system performance considerably During grid faults unbalanced currents cause negative effects like overheating problems and mechanical stress due to high torque pulsations that can damage the rotor shaft gearbox or blade assembly Therefore the dynamic model of the DFIG driven by a wind turbine during grid faults has been analyzed and developed using the method of symmetrical components The dynamic performance of the DFIG during unbalanced grid conditions is analyzed and described in detail using digital simulations A novel fault ride through FRT capability is proposed i e the ability of the power system to remain connected to the grid during faults with suitable control strategy in this thesis In this scheme the input mechanical energy of the wind turbine during grid faults is stored and utilized at the moment of fault clearance instead of being dissipated in the resistors of the crowbar circuit as in the existing FRT schemes

Advanced Control of Variable Speed Wind Turbine Based on Doubly-fed Induction

Generator Lei Wang,2012 This thesis deals with the modeling control and analysis of doubly fed induction generators DFIG based wind turbines DFIG WT The DFIG WT is one of the mostly employed wind power generation systems WPGS due to its merits including variable speed operation for achieving the maximum power conversion smaller capacity requirement for power electronic devices and full controllability of active and reactive powers of the DFIG The dynamic modeling of DFIG WT

has been carried out at first in Chapter 2 with the conventional vector control VC strategies for both rotor side and grid side converters. The vector control strategy works in a synchronous reference frame aligned with the stator flux vector and became very popular for control of the DFIG. Although the conventional VC strategy is simple and reliable, it is not capable of providing a satisfactory transient response for DFIG WT under grid faults. As the VC is usually designed and optimized based on one operation point, thus the overall energy conversion efficiency cannot be maintained at the optimal point when the WPGS operation point moves away from that designed point due to the time-varying wind power inputs. Compared with VC methods which are designed based on a linear model obtained from one operation point, nonlinear control methods can provide consistent optimal performance across the operation envelope rather than at one operation point. To improve the asymptotical regulation provided by the VC which can't provide satisfactory performance under voltage sags caused by grid faults or load disturbance of the grid, input-output feedback linearization control (IOFLC) has been applied to develop a fully decoupled controller of the active/reactive powers of the DFIG in Chapter 3. Furthermore, a cascade control strategy is proposed for power regulation of DFIG WT which can provide better performance against the varying operation points and grid disturbance. Moreover, to improve the overall energy conversion efficiency of the DFIG WT, FLC-based maximum power point tracking (MPPT) has been investigated. The main objective of the FLC-based MPPT in Chapter 4 is to design a global optimal controller to deal with the time-varying operation points and nonlinear characteristic of the DFIG WT. Modal analysis and simulation studies have been used to verify the effectiveness of the FLC-based MPPT compared with the VC. The system mode trajectory, including the internal zero dynamic of the FLC MPPT, are carefully examined in the face of varied operation ranges and parameter uncertainties. In a realistic DFIG WT, the parameter variability, the uncertain and time-varying wind power inputs are existed. To enhance the robustness of the controller, a nonlinear adaptive controller (NAC) via state and perturbation observer for feedback linearizable nonlinear systems is applied for MPPT control of DFIG WT in Chapter 5. In the design of the controller, a perturbation term is defined to describe the combined effect of the system nonlinearities and uncertainties and represented by introducing a fictitious state in the state equations. As follows, a state and perturbation observer is designed to estimate the system states and perturbation, leading to an adaptive output feedback linearizing controller which uses the estimated perturbation to cancel system perturbations and the estimated states to implement a linear output feedback control law for the equivalent linear system. Case studies, including with and without wind speed measurement, are carried out and proved that the proposed NAC for MPPT of DFIG WT can provide better robustness performance against the parameter uncertainties. Simulation studies for demonstrating the performance of the proposed control methods in each chapter are carried out based on MATLAB/SIMULINK.

DFIG-based Wind Power Conversion System Connected to Grid Akshay Kumar, 2014-08-14 Master's Thesis from the year 2014 in the subject Engineering Power Engineering grade 7/8 Ajay Kumar Garg Engineering College course M.Tech language English abstract Wind generation has

become the most important alternate energy source and has experienced increased progress in India during the past decade. While it has great potential as an alternative to less environmentally friendly energy sources, there are various technical challenges that cause wind to be considered negatively by many utilities. Wind energy conversion systems suffer from the fact that their real power generation is closely dependent on the local environmental conditions. The Doubly Fed Induction Generator (DFIG) based wind turbine with variable speed variable pitch control scheme is the most popular wind power generator in the wind power industry. This machine can be operated either in grid connected or standalone mode. In this thesis, a detailed electromechanical model of a DFIG based wind turbine connected to power grid as well as separately operated wind turbine system with different sub systems is developed in the MATLAB SIMULINK environment and its equivalent generator and turbine control structure is realized. In this regard, following configurations have been considered: DFIG with Battery storage sub system, DFIG with Buck Boost converter, DFIG with transformer, DFIG with 3 winding transformer. Addition of battery storage and buck boost converter sub systems into the system enables not only dispatching of generator power but also decreases the variability in their reactive power requirements. The full control over both active and reactive power is possible by the use of transformer between DFIG and rotor side converter. The steady state behavior of the overall wind turbine system is presented and the steady state reactive power ability of the DFIG is analyzed. It has been shown that major part of the reactive power should be supplied from rotor side converter to reduce the overall rating of the generator. The DFIG with above mentioned sub systems is connected to grid. The total harmonic distortion analysis and efficiency are carried out. It is found that DFIG with transformer in between machine and rotor side converter has lowest THD 2.29% and DFIG with 3 winding transformer has maximum efficiency above 93%.

Modeling, Analysis and Enhancement of the performance of a Wind Driven DFIG During steady state and transient conditions Mohmoud Mossa, 2014-01-01

Recently wind electrical power systems are getting a lot of attention since they are cost competitive, environmentally clean and safe renewable power source as compared with the fossil fuel and nuclear power generation. A special type of induction generator called a doubly fed induction generator (DFIG) is used extensively for high power wind applications. They are used more and more in wind turbine applications due to the ease of controllability, the high energy efficiency and the improved power quality. This research aims to develop a method of a field orientation scheme for control both the active and the reactive powers of a DFIG that are driven by a wind turbine. Also the dynamic model of the DFIG driven by a wind turbine during grid faults is analyzed and developed using the method of symmetrical components. Finally

this study proposes a novel fault ride through FRT capability with a suitable control strategy i.e. the ability of the power system to remain connected to the grid during faults
