Part I: Strength and Behavior of Reinforced Concrete Beams and Frames**, 1958 The results of 57 tests on simply supported beams and 24 tests on frame members are described and correlated in this report

The main object of these tests was to study the behavior and strength in shear of reinforced concrete members a few tests were intended to study the flexural strength of under reinforced members under axial load and bending The ultimate objective of the test program was to obtain information which would permit the development of more rational design criteria for reinforced concrete box culverts Fundamental knowledge was first acquired through tests of simply supported beams under various conditions of loading And finally tests were made on 24 frames under conditions simulating closely those in the horizontal member of a box culvert section three of these frames had web reinforcement in the form of bent bars The following major variables were studied during the course of the investigation type of loading concrete strength steel percentage ratio of span length to effective depth ratio of shear span to effective depth and ratio of axial to vertical load The simply supported beams were tested under one or two concentrated loads or under uniform load

Concrete Box-culvert Design Maher K. Tadros, 1986 This is a study of the analysis and design of reinforced concrete box culverts RCB commonly used as underground conduits in Nebraska Three major areas were emphasized 1 soil pressures 2 live loads and 3 design procedures *Structural Investigation of a Fiber Reinforced Precast Concrete Box Culvert*, 2005 This investigation of a pre cast concrete box culvert was undertaken to determine the suitability of replacing conventional reinforcing steel with a fiber reinforced concrete It can be predicted that fiber reinforced concrete will provide the culvert with a strength and durability that are equivalent to or exceed those provided by the culvert reinforced with conventional reinforcing steel The use of the fiber reinforcement would result in a significant reduction in the labor costs when compared to the fabrication of a pre cast concrete culvert unit reinforced with conventional reinforcing steel LJB Inc in conjunction with the University of Cincinnati has performed a full scale load test of a 12 foot span 6 foot tall pre cast box culvert reinforced with monofilament polypropylene fibers The objective was to assess the behavior of the fiber reinforced culvert both experimentally and analytically and to determine the feasibility of using the fiber reinforced culvert in place of the commonly used standard reinforced unit During construction of the bridge the fiber reinforced culvert was load tested utilizing a load actuator mounted on top Strains and deflections were recorded using instruments mounted at strategic locations Recorded strains and deflections were compared to theoretical values obtained from three finite element models The results of this investigation generated positive results However due to the presence of a crack that had developed near the mid span of the culvert prior to load testing further testing is suggested Even with this crack the results suggest the future success of the use of fibers to replace conventional reinforcing steel

Load Effect in Reinforced Concrete Box Culverts Under Soil Fill Sarah Orton, Erik Loehr, Andrew Boeckmann, 2014 The objective of this study is to determine the effects of live load truck loads on bridge size spans greater than 20 ft reinforced concrete box culverts under soil fills of different thickness Testing results show that live load effect does diminish with increasing fill depth The AASHTO LRFD and LFD Standard Specifications were both overly conservative in predicting strains and displacements compared to the field data for fill depths less than 8 ft At above 6 ft of fill the measured effect of the live load was less than 10% of the dead load effect This could be considered as a point at which to ignore the live load effect and therefore not load rate the culvert

Improved Load Distribution for Load Rating of Low-fill Box Structures, 2013 Reinforced concrete box culverts are mostly used at shallow depths Periodic evaluation of their load carrying capacities is required for load rating of the culvert by determining a rating factor RF or truck tonnage of an HS truck The rating factor is defined as the capacity of the structure minus the dead load demand and then divided by the live load demand All the state DOTs are required to inspect and assess culvert conditions and capacities by load rating in every two years The distribution of live loads on the top slab of a box culvert plays a major role in determining the rating factor of the culvert The current AASHTO guidelines do not consider the effects of pavements present above the fill while determining the load distribution The distribution of the wheel load through a pavement may be different from that suggested by the current AASHTO guidelines In addition to the pavement effect the fill conditions i e fill thickness and fill modulus may affect the load distribution Currently there is lack of a design method to address the load distribution when a pavement is present above the fill In this research two field tests were carried out on the concrete box culverts under rigid and flexible pavements respectively The finite difference numerical models of the test culverts were created in the Fast Lagrangian Analysis of Continua in three dimensions FLAC3D software and were verified against the field test results The verified finite difference models of the culverts were used for a parametric study to analyze the effects of pavement type i e flexible and rigid pavement pavement thickness fill depth and culvert span on the pressure distribution The material properties and boundary conditions used in the models for the parametric study were similar to those used in the verified models The parametric study demonstrated that the intensity of the distributed vertical pressure on the top slab of the culvert gradually decreased as the pavement thickness increased The vertical pressure under a rigid pavement was lower than that under a flexible pavement at the same pavement thickness Within the range of the fill depth covered in this study the intensity of vertical pressure decreased gradually with an increase of the fill depth over the culvert The effect of the traffic load on the vertical pressure on the culvert was more significant at the lower fill depth and gradually decreased with the increase of the fill depth The calculated vertical pressure decreased when the culvert span was increased from 1.8 to 5.4 m for a constant top slab thickness of the culvert However when the top slab

thickness of the culvert increased the vertical pressure at the larger span was close to that at the small span The effect of the culvert span on the vertical pressure was negligible if the thickness of the top slab was properly designed The maximum vertical pressures obtained from the numerical analyses were compared with those calculated using the distribution formulae in the AASHTO guidelines The comparisons showed that the current AASHTO guidelines over estimated the pressure for low fill culverts under a pavement Simplified methods were developed in this study to estimate the vertical pressures under rigid and flexible pavements that closely match the experimental and numerical results Proposed revisions to the current AASHTO LRFD Bridge Design Specifications are suggested and included in the appendix of this report **Evaluation of Precast**
