Some Historical Remarks

The idea of optical communications by transmitting speech through a beam of light is as ancient as 1880 when Alexander Graham Bell had invented the "photophone", shortly after the invention of telephone. With the advent of the laser and LED in the early 1960s, numerous possibilities for practical applications of light-wave communications became apparent. By utilizing only a small part of the visible or infrared radiation frequencies, a single light-wave system could simultaneously carry the telephone conversations of a nationwide population. However, it was realized very soon, unlike the microwave and radio-relay systems, the projection of laser beams through the atmosphere is unrealistic due to inevitable interruptions by atmospheric disturbances like fog, storms, rain, snow etc. So, the main challenge of the optical engineers was to identify an appropriate medium through which light can be transmitted over long distance. In 1966, K. C. Kao and G. A. Hockman of Standard Telecommunications reported, after extensive measurements of different commercially available bulk glass samples, optical fibers can be potential signal transmission medium for long distance communications if absorption and scattering losses can be brought down to below 20 dB/km at operating wavelength by removing impurities of the glass and simultaneously transmitting signals at longer wavelengths¹. This groundbreaking suggestion stimulated tremendous progress in the development of processing

techniques to fabricate light guides which exhibit low attenuation, high bandwidth, good dimensional control and excellent mechanical properties. In order to obtain the light guidance over miles, silica optical fibers were designed in a way that the light should confine into the central part of the fiber and may not leak from the outer surface. Each fiber usually consists of three layers: i) Coating, ii) Clad and iii) Core. The outer layer is a polymer coating to protect environmental hazards. Within the protective coating, the glass fiber itself has a core region with a higher refractive index (RI) than that of its surrounding cladding so that light beams can be transmitted infinitely due to the effect of total internal reflection. In the mid-1960s, various laboratories around the world started to develop significant low loss optical fibers by eliminating impurities such as iron, chromium, vanadium, water etc. The breakthrough came when low loss glass fibers were prepared at Corning Glass Works in 1970 by R. D. Maurer with a loss of 17 dB/km at wavelength of 632.8 μm^2 . A dramatic improvement in process efficiency as well as attenuation was realized in 1974 with the invention of Modified Chemical Vapor Deposition (MCVD) technique by J. B. MacChesney at Bell Lab². Single mode passive silica fibers with losses as low as 0.36 dB/km at 1.3 μm and 0.2 dB/km at 1.55 μm were demonstrated. By early 1980s, this MCVD process had been widely adopted and accounted for the dominant fraction of the optical fiber produced throughout the world. Even at this low loss value, laser beams can only be transmitted over few kilometers after which amplification is needed due to weakening of the input signal. The second breakthrough for the telecommunication industries was realized after designing of Erbium (Er) doped fiber amplifier (EDFA) which provides signal
