Abstract- Under ground-fault conditions, the flow of current will result in voltage gradients within and around the substation, not only between structures and nearby earth, but also along the ground surface. In a properly designed system, this gradient should not exceed the limits that can be tolerated by the human body. The purpose of a ground mat study is to provide for the safety and well-being of anyone that can be exposed to the potential differences that can exist in a station during a severe fault. The general requirements for industrial power system grounding are similar to those of utility systems under similar service conditions. The differences arise from the specific requirements of the manufacturing or process operations. Some of the factors that are considered in a ground-mat study are the following:

- a) Fault-current magnitude and duration
- b) Geometry of the grounding system
- c) Soil resistivity
- d) Probability of contact
- e) Human factors such as
 1. Body resistance
 2. Standard assumptions on physical conditions of the individual

I. INTRODUCTION

In designing and construction of an electric substation, one of the most important issues that must be considered is designing of protective system to the earth. Flow of the earth system, cause voltage gradients ground level which cause different parts of the earth and the reference (ground round). The potential difference should be carefully and automatically designed. This may have enough voltage to reach the safety of people in place and causes risk. In this situation, people feel exposed to high voltages between the location of two steps (Step voltage) and also if a person at this moment in contact with the ground is a metal device, the voltage between that point and exposed earth place your foot (contact voltage).

Earth system must be designed so that the order should contact voltages and maximum values possible

step event and substation where conditions are faulty. The maximum values of contact and step voltages tolerated human body should be less.

A method for designing the earth system is based on the use of the land network in the same intervals. The results using this method largely increases system costs and the need for land will be provided in addition to better meet the safety conditions, will prevent the additional costs.

In the past, papers presented for optimizing the land in these articles, but only for optimizing the parameters are considered, the length conductors earth system. In reference [1] related to voltage changes and call the number step conductors earth system to determine efficiency in reducing conductors increased contact and step voltages provided the tolerance values, has been compared to evaluate safety. In references [2, 3 and 4] study on compression ratio and its relationship with the conductors and the voltage step was to contact and appropriate compression ratio achieved with minimal contact voltage compared with the values of tolerance not to evaluate safety is. In reference [5] the help of genetic algorithm optimization of the network but the number conductors and earth have already been fixed and the purpose of minimizing voltage contact, but not compared with the values of tolerance. In reference [6] for optimizing the relationship between the earths system during consecutive meshes is considered. But the only optimization variable, the total length of network Conductors earth.

In references [7-9] genetic algorithm optimization performed by the reference [8]. The vertical rods considered but the authorities only as total length conductors earth system optimization point is variable. Considering the above observation is that all articles provided for optimizing the system, earth, only during the earth system as a whole Conductors variable optimization is considered if the studies done, other parameters of the immune system of the earth effective.

from the IEEE Standard 80 2000 calculations will be used to determine whether the substation grounding is safe by design. The information provided here will help to ensure a safe environment for those working in or around the substation while protecting equipment from dangerous electrical shock under normal and faulted condition. **Substation Grounding** Inna Baleva, California State University, Sacramento, 2012. Designing a proper substation grounding system is quite complicating. Many parameters affect its design. In order for a grounding design to be safe it needs to provide a way to carry the electric currents into the ground under both normal and faulted conditions. Also it must provide assurance that a person in the vicinity would not be endangered. The grounding portion of substation design will be explored. In order to properly plan and design the grounding grid calculations of the following will be done: maximum fault current, grid resistance, grid current, safe touch and step voltages, ground potential rise as well as expected touch and step voltage levels. Background information and guidelines to design a substation grounding grid will be provided. A set of equations will be presented to calculate whether the design is safe and finally an example will be provided that can be used as a template. Sources of Data: IEEE Std 80 2000. Joy, **Optimum Design of Grounding System of High Voltage Substations** Ossama Gouda, 2011-03. The main purpose of this article is to study the optimum design of grounding system of high voltage substations by using artificial neural network. The proposed study will implement the following important contributions: 1 Performance of grounding system under uniform and non uniform soil resistivity 2 Grounding by using equal and non equal spacing grids studying the performance of non equal spacing grid in case of uniform and non uniform soil 3 Grounding by grids and rods in non uniform soil and unequally spaced grids 4 Safety analysis of grounding grid with different structures 5 Designing of ANN as a tool to select the optimum grounding system 6 Performance of grounding system under transient conditions. *A Study of HV Electric Power Substation Grounding System Design* Benjamin Kinyua Muita, 1983. *Grounding Systems for Electric Substations in Non-Uniform Soil* Ahmed Thabet Mohamed, Osama El-Sayed Gouda, 2014-11-14. As the number and complexity of AC substation increase the need for accurate design procedures for the grounding systems becomes more important both from safety point of view and from financial considerations. The boring test samples and other geological investigations often provide useful information on the presence of various layers and the nature of soil material as its resistivity and the range of values at the site. THIS BOOK discuss New theoretical developed methods for calculation the earthing resistance and earth surface potentials of variant electric substation earthing systems i.e starting from a grid consists of one mesh or rod to a final design consisting of many regular meshes or rods respectively. An experimental work is carried out on an improved scale model to study the behavior of earthing systems in non uniform soil structure. *Grounding Grid Design for High Voltage Substations* Farhan bin Hanaffi, 2016. An electrical grounding system is an important element to ascertain a safe environment for both humans and equipment during fault or transient conditions.

The performance of grounding systems under lightning current is quite different from the conventional frequency based power In order to understand the grounding grid behaviour under lightning current researchers typically carry out experiments on actual grounding systems or on laboratory scaled models Although experiments can provide insights of the actual grounding operation the shortcoming is that a large area of lab space is required which reflects into high costs As an alternative computer simulation has been introduced and can be categorised into three different approaches namely circuit approach transmission line approach or electromagnetic approach In this work the simulations are performed based on the electromagnetic approach under three dimensions 3D mode due to its accurate results For further understanding a comparison between circuit and electromagnetic approaches is also carried out where the resulting outcome shows that the circuit approach underestimates the impulse impedance at injection point compared with simulations by the electromagnetic approach When the electromagnetic approach is applied a finite element method is used to solve the partial differential electromagnetic equations in the time domain Thereafter the simulations results are validated with the existing published results covering the electromagnetic simulations by using the method of moment MOM and as well as actual field experiments In addition simulations are performed to understand the effect of different parameters including lightning current soil parameters grounding design and location of injection point of lightning current Moreover a comparison study is carried out for potential rise between power frequency and impulse current at different grid sizes The study shows the potential generated at injection point for both current and saturation point when the grid size reaches a certain point It s important to consider both types of current to get better grounding grid design Besides that empirical equations are used out to calculate the effective area under lightning conditions where the effect of the down conductor is taken into consideration as part of the grounding model The effective area is an important parameter for the optimization of the grounding grid design when increasing grounding size does not improve the impulse impedance Transient ground potential rise TGPR above the ground is another interesting parameter to analyse In this work a good correlation is shown between the effective area and the impulse impedance at the injection point with rising transient ground potential It is found that the TGPR is larger when it is closer to the injection point but only lasts for a few microseconds Step voltage evaluations are performed for different standing positions of the human above the grid including the distance of the step voltage location from the injection point and the effect of grid size to step voltage value

Substation Grounding Optimization Vadim Balev, Pravesh Charan, California State University, Sacramento, 2013 Substation grounding is a critical part of the overall electric power system It is designed to not only provide a path to dissipate electric currents into the earth without exceeding the operating limits of the equipment but also provide a safe environment for any people that are in the vicinity Design of a proper grounding system will be discussed as well as performing of calculations necessary to ensure a safe design Aspects of soil resistivity measurements area of the ground grid calculation of tolerable limits of current to the body typical shock situations

tolerable touch and step voltages maximum fault current grid resistance grid current ground potential rise and benefits of surface materials will be discussed Simulation software will also be discussed and its functionality in a step by step manner Sources of Data IEEE Std 80 2000 was used as the primary source of information Conclusions Reached An adequate grounding grid has been designed using concepts outlined in IEEE Std 80 2000 and applied into programming and simulating results in MATLAB *High Voltage Grounding Systems* Gary Gilbert,2011 Minimization of Construction Costs of Substation Grounding Grids In every electrical installation one of the most important aspects is adequate grounding in particular the grounding of high voltage substations to protect people and equipment in the event of an electrical fault Well designed grounding systems ensure the performance of power systems and safety of personnel It is desirable that the substation grounding provides a near zero resistance to remote earth The prevailing practice of most utilities is to install a grid of horizontal ground electrodes buried bare copper conductors supplemented by a number of vertical ground rods connected to the grid and by a number of equipment grounding mats and interconnecting cables The grounding grid provides a common ground for the electrical equipment and for all metallic structures at the station It also limits the surface potential gradient Currently the IEEE 80 2000 standard for substations grounding limits the determination of the grounding parameters namely step touch and ground potential rise to that of a uniform soil model unless the Sunde graphical method is used With the Sunde graphical method it relies on interpretation to obtain a two layer soil model Without the use of the graphical method the IEEE 81 1983 has several empirical equations that can be used for the two layer model however these equations rely on the use of images which retard the speed of calculations to the point where the overall optimization of the grounding grid with respect to size and shape has yet to be determined The goal of the thesis was to improve upon the current restrictions for the grounding grid design while minimizing the material i e copper conductors and installation costs of a grid

Popovic,2018-02-20 Practical Methods for Analysis and Design of HV Installation Grounding Systems gives readers a basic understanding of the modeling characteristics of the major components of a complex grounding system One by one the author develops and analyzes each component as a standalone element but then puts them together considering

their mutual disposition or so called proximity effect This is the first book to enable the making and analysis of the most complex grounding systems that are typical for HV substations located in urban areas that uses relatively simple mathematical operations instead of modern computers Since the presented methods enable problem solving for more complex issues than the ones solved using National IEC and or IEEE standards this book can be considered as an appendix to these standards Develops general equations of lumped parameter ladder circuits Includes the analytical expression for determination of ground fault current distribution for a fault anywhere along a cable line Presents measurement and analytical methods for the determination of actual ground fault current distribution for high voltage substations located in urban areas Provides the analytical procedure for the determination of the critical ground fault position for faults appearing in outgoing transmission lines Defines testing procedure for the correct evaluation of grounding systems of substations located in urban areas
