

Direct Proportion

Direct proportion is a type of proportionality relationship; as one variable increases/decreases, so does the other variable.

To calculate an unknown value that is directly proportional to another, we use a multiplier, known as the **constant of proportionality**.

The symbol $\propto$ means 'is proportional to'.

If y is **directly proportional to** x , we can write this relationship as $y \propto x$.

As $y \div x = k$ where k is the constant of proportionality, we can deduce the direct proportion formula:

$$y = kx$$

Direct Proportion Problems Solutions:

Solution of Superlarge Problems in Computational Mechanics James H. Kane, 2012-12-06 There is a need to solve problems in solid and fluid mechanics that currently exceed the resources of current and foreseeable supercomputers. The issue revolves around the number of degrees of freedom of simultaneous equations that one needs to accurately describe the problem and the computer storage and speed limitations which prohibit such solutions. The goals of this symposium were to explore some of the latest work being done in both industry and academia to solve such extremely large problems and to provide a forum for the discussion and prognostication of necessary future directions of both man and machine. As evidenced in this proceedings we believe these goals were met. Contained in this volume are discussions of iterative solvers and their application to a variety of problems e.g. structures, fluid dynamics and structural acoustics, iterative dynamic substructuring and its use in structural acoustics, the use of the boundary element method both alone and in conjunction with the finite element method, the application of finite difference methods to problems of incompressible turbulent flow and algorithms amenable to concurrent computations and their applications. Furthermore, discussions of existing computational shortcomings from the big picture point of view are presented that include recommendations for future work.
